

EURUSD 07:00-19:00 NY Strategy Research Report

1. Executive Summary

Tu objetivo es correcto: no buscar “ideas”, sino un **universo de hipótesis** con lógica de mercado, reglas objetivas y filtros anti-autoengaño. El mayor riesgo no es falta de señales, sino construir estrategias muy parecidas entre sí, sobreajustadas a una submuestra, o demasiado sensibles a costos y spreads. La mejor ruta para EURUSD intradía es combinar cinco familias: expansión de volatilidad, reversión a la media, rupturas/fallos de sesión, pullbacks de tendencia, y edges temporales/news-aware. Un marco serio de validación debe separar claramente smoke test, train-only, walk-forward y holdout, con freeze de parámetros antes de tocar 2025/2026. También conviene tratar la estrategia “barrido de liquidez + cambio de estructura” como una sola clase de edge, y priorizar ideas de baja correlación para construir cartera, no un único sistema frágil. En prop/FTMO, la supervivencia depende tanto del control de DD y exposición como del PF.

2. Assumptions

Asumo que tenés tick data limpia de EURUSD desde 2015 a 2026, con bid/ask o al menos spread realista, y calendario de noticias macro usable. Asumo que podés reconstruir sesiones NY con precisión horaria y que podés simular costos de ejecución de forma conservadora. No asumo que el edge exista; solo que cada hipótesis es **testable** y podría sobrevivir si la estructura de mercado la respalda. No asumo que holdout 2025/2026 deba tocarse antes de madurar la metodología. Tampoco asumo que una estrategia con buen PF en train vaya a ser robusta: eso debe probarse.

3. Strategy Universe

Rank	Strategy	Category	Session	Expected Frequency	Complexity	Overfit Risk	Cost Sensitivity	Correlation Risk	Priority Score
1	London Compression Breakout	Volatility expansion	07:00-10:30 NY	Medium	Medium	Medium	Medium	Low	92
2	NY Open Range Expansion	Volatility expansion	08:30-11:30 NY	Medium	Medium	Medium	Medium	Low	90
3	Pre-Data Compression Release	Volatility expansion	08:00-10:00 NY	Low-Med	Medium	Medium	High	Low	88
4	Session VWAP Dislocation	Mean reversion	07:00-15:00 NY	Medium	Medium	High	Medium	Medium	87
5	ATR Stretch Snapback	Mean reversion	07:00-19:00 NY	High	Low-Med	Medium	High	Medium	84
6	Asia-to-NY Range Failure	Session breakout/failure	07:00-09:30 NY	Medium	Medium	Medium	Medium	Low	83

Rank	Strategy	Category	Session	Expected Frequency	Complexity	Overfit Risk	Cost Sensitivity	Correlation Risk	Priority Score
7	Early NY False Breakout Fade	Session breakout/failure	07:00-10:00 NY	Medium	Medium	High	Medium	Low	82
8	Late-Session Trend Pullback	Trend pullback	12:00-18:30 NY	Low-Med	Medium	Medium	Medium	Medium	81
9	Post-Impulse Pullback Continuation	Trend pullback	08:30-16:00 NY	Medium	Medium	Medium	Medium	Medium	80
10	Pre-London Trend Alignment	Trend pullback	07:00-08:30 NY	Low	Medium	Medium	Medium	Medium	78
11	Post-NFP Stabilization Breakout	Post-news	08:45-10:00 NY	Low	Medium	High	High	Low	77
12	FOMC Drift-Reentry	Post-news	14:05-16:30 NY	Low	Medium	High	High	Low	76
13	Monday NY Mean Reversion	Time-of-day/statistical	07:00-12:00 NY	Low-Med	Low	Medium	Medium	Medium	75
14	Friday Afternoon Flattening Edge	Time-of-day/statistical	13:00-18:30 NY	Medium	Low	Medium	Low	Medium	74
15	Volatility Regime Breakout Filter	Hybrid original	07:00-19:00 NY	Low-Med	Medium	Medium	Medium	Low	79
16	Trend + Compression Pullback Hybrid	Hybrid original	07:00-19:00 NY	Medium	Medium	Medium	Medium	Medium	80
17	Opening Sweep Failure	Mean reversion	07:00-09:00 NY	Medium	Medium	High	Medium	High	73
18	Midday Quiet Range Reversion	Mean reversion	11:00-14:00 NY	Medium	Low	Medium	High	Medium	71
19	Session High/Low Rejection	Session breakout/failure	07:00-19:00 NY	Medium	Medium	Medium	Medium	Medium	82
20	Time-Boxed Trend Exhaustion	Trend pullback	15:00-18:50 NY	Low	Medium	Medium	Medium	Medium	77

4. Full Strategy Specifications

1) London Compression Breakout

Market Phenomenon: Pre-London volatility compression often resolves into directional expansion.

Quant Hypothesis: If the first NY hours trade inside a narrow range after prior-session compression, the next impulsive move tends to continue beyond the range.

Why It Could Work on EURUSD: EURUSD often transitions from low-volatility drift into expansion around European/US overlap, especially when prior range is tight and liquidity is building.

Trading Window: 07:00-10:30 NY.

Timeframe: M5 with M15 context.

Required Data: OHLC, ATR, session high/low, spread, optional news filter.

Long Entry Rules:

- Define compression as prior 6 bars on M15 with range $\leq 0.6 * 20\text{-day intraday median M15 range}$.
- Price must break above the compression high by at least $0.2 * \text{ATR}(M5,14)$.
- Close of breakout bar above range high.
- Spread $\leq$ threshold.

Short Entry Rules: Mirror for downside.

Stop Loss Logic: Opposite side of compression range or $1.0 * \text{ATR}(M5,14)$, whichever is tighter but not below a minimum pip floor.

Take Profit Logic: TP1 at 1R, TP2 at 2R or trailing by 1 ATR(M5,14).

Trade Management: Move to BE after 0.8R; time stop after 12 bars; only one trade per direction per session.

Filters: No high-impact news ± 15 min; ATR regime above low-vol floor; avoid Friday after 15:30 NY.

Initial Parameters: Compression lookback 6 M15 bars; breakout buffer 0.2 ATR; BE at 0.8R.

Expected Frequency: 2-6 trades/week.

Why It Might Fail: False breakouts around thin liquidity, news contamination, and regime shifts.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: Low; this is expansion, not stop-run reversal.

Backtest Acceptance Criteria: At least 150 trades, PF > 1.30 train, stable by year, slippage +0.5 pip should not destroy expectancy.

Pseudocode:

```
if session in window and no_news:
    if compression_detected and close > range_high + buffer:
        enter_long()
    if compression_detected and close < range_low - buffer:
        enter_short()
manage_risk()
```

2) NY Open Range Expansion

Market Phenomenon: First post-open directional auction often expands from the opening range.

Quant Hypothesis: A validated opening range break after an initial balance period has positive continuation odds.

Why It Could Work on EURUSD: NY open often reprices FX liquidity after US participation begins, especially if Europe already set a directional bias.

Trading Window: 08:30-11:30 NY.

Timeframe: M1 entry, M5 context.

Required Data: OHLC, opening range, spread, news calendar.

Long Entry Rules:

- Build opening range from 08:30 to 08:45 NY.
 - Long if price breaks OR high by $> 0.15 \text{ ATR}(M5,14)$ and M1 closes above OR high.
 - Optional bias filter: M15 close above VWAP or EMA20.
- Short Entry Rules: Mirror below OR low.
- Stop Loss Logic: Other side of OR plus spread buffer.
- Take Profit Logic: 1.5R fixed or trail after 1R using M1 swing lows/highs.
- Trade Management: One trade per direction max; time stop at 60 min.
- Filters: Avoid major news within 10 min; spread below median*1.2; only if opening range width is not extreme.
- Initial Parameters: OR 15 min; breakout buffer 0.15 ATR; time stop 60 min.
- Expected Frequency: 1-4 trades/week.
- Why It Might Fail: Whipsaw in balanced days, especially if open range is too narrow or too wide.
- Overfitting Risk: Medium.
- Cost Sensitivity: Medium.
- Correlation With Liquidity Sweep Strategy: Low.
- Backtest Acceptance Criteria: PF > 1.35 train, not concentrated in one quarter, and with stable results across Fed weeks/non-Fed weeks.
- Pseudocode:

```
or_high, or_low = range(08:30, 08:45)
if m1_close > or_high + buf and no_news:
    long
if m1_close < or_low - buf and no_news:
    short
```

3) Pre-Data Compression Release

Market Phenomenon: Markets compress before scheduled macro releases and then release volatility.

Quant Hypothesis: If pre-event range is unusually tight, the first post-event move has higher continuation probability than random.

Why It Could Work on EURUSD: EURUSD is highly sensitive to scheduled US data; pre-release positioning and liquidity withdrawal create expansion risk.

Trading Window: 08:00-10:00 NY around scheduled high-impact US data.

Timeframe: M1.

Required Data: News calendar with timestamps, bid/ask, OHLC.

Long Entry Rules:

- No trade before event.
 - If first 1-3 minutes after release close above event high and spread normalizes, go long.
 - Require pre-event 15-min range $\leq$ rolling 20th percentile.
- Short Entry Rules: Mirror below event low.
- Stop Loss Logic: Opposite side of event range or fixed pip cap.
- Take Profit Logic: 1.5R to 3R depending on event class, partial at 1R.
- Trade Management: No entry in first 15-30 seconds; hard time stop 30-45 min; exit before second-tier reversal window if opposite impulse forms.
- Filters: High-impact only; ignore if spread $>$ threshold post-release; skip if release occurs inside already high-vol regime.
- Initial Parameters: Pre-event window 15 min; release confirmation 1-3 min.
- Expected Frequency: Low, 1-3 trades/month.
- Why It Might Fail: Slippage, whipsaws, and event-specific instability.
- Overfitting Risk: High.
- Cost Sensitivity: High.
- Correlation With Liquidity Sweep Strategy: Low.

Backtest Acceptance Criteria: Needs many events across years, stable by event type, conservative cost assumptions.

Pseudocode:

```
if high_impact_event and pre_event_range_small:
    wait 1-3 minutes
    if close > event_high and spread_normal:
        long
```

4) Session VWAP Dislocation

Market Phenomenon: Price stretched far from VWAP during liquid sessions often reverts toward VWAP.

Quant Hypothesis: Large intraday VWAP deviations in liquid conditions mean-revert more often than they trend.

Why It Could Work on EURUSD: EURUSD is deeply liquid and often trades as an efficient mean-reverting market outside strong news/trend days.

Trading Window: 07:00-15:00 NY.

Timeframe: M5.

Required Data: VWAP, OHLC, spread, ATR, session high/low.

Long Entry Rules:

- Price below VWAP by $> 1.5 * \text{intraday std-dev}$ or $> 1.2 \text{ ATR}(M15,14)$.
- M5 candle shows rejection lower wick and closes back above prior bar low.
- No strong downtrend regime on M15.

Short Entry Rules: Mirror above VWAP.

Stop Loss Logic: Beyond local extreme or 1R.

Take Profit Logic: VWAP first; then 1.5R if momentum supports.

Trade Management: Partial at VWAP, BE at 0.75R, time stop 8-12 bars.

Filters: Avoid trend days, news ± 30 min, and first 10 min after NY open.

Initial Parameters: Deviation threshold 1.5 sigma, 1.2 ATR backup.

Expected Frequency: 3-10 trades/week.

Why It Might Fail: Strong trend days can keep price away from VWAP for long periods.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: Medium.

Backtest Acceptance Criteria: Strong separation by trend vs non-trend regime, PF robust after excluding top news days.

Pseudocode:

```
if abs(price-vwap) > threshold and regime_not_trending:
    if rejection_candle():
        fade_to_vwap()
```

5) ATR Stretch Snapback

Market Phenomenon: Short-term overextension tends to snap back when range exceeds typical session volatility.

Quant Hypothesis: Extreme intraday stretch relative to ATR is followed by a statistically favorable retracement.

Why It Could Work on EURUSD: EURUSD often overextends during liquidity bursts and then mean-reverts when urgency fades.

Trading Window: 07:00-19:00 NY.

Timeframe: M1/M5.

Required Data: ATR, OHLC, spread, session stats.

Long Entry Rules:

- Price has fallen $> 1.8 \text{ ATR}(M15,14)$ from a local intraday pivot.
- Momentum decelerates: two consecutive lower lows fail to extend by more than 20% of prior leg.
- Enter on bullish reversal close.

Short Entry Rules: Mirror for upside stretch.

Stop Loss Logic: Beyond stretch extreme by fixed ATR fraction.

Take Profit Logic: $1R-2R$, or 50% retrace of stretch leg.

Trade Management: Time stop 10 bars; optional BE at $0.6R$.

Filters: Skip during strong trend regimes, around news, or when ATR regime is elevated in the direction of stretch.

Initial Parameters: Stretch threshold 1.8 ATR; deceleration test 2 bars.

Expected Frequency: 4-12 trades/week.

Why It Might Fail: Catching a real trend continuation instead of exhaustion.

Overfitting Risk: Medium.

Cost Sensitivity: High.

Correlation With Liquidity Sweep Strategy: Medium.

Backtest Acceptance Criteria: Needs robustness across regimes and positive expectancy after conservative slippage.

Pseudocode:

```
if extension > 1.8*ATR and momentum_fades:
    enter_reversal()
```

6) Asia-to-NY Range Failure

Market Phenomenon: Asian-session range often fails when NY participation enters.

Quant Hypothesis: Breaks of the prior low-volatility range during NY are more likely to fail or extend only after confirmation.

Why It Could Work on EURUSD: The session handoff often re-prices ranges built in thinner liquidity.

Trading Window: 07:00-09:30 NY.

Timeframe: M5.

Required Data: Session highs/lows, OHLC, spread.

Long Entry Rules:

- Price sweeps below Asian low by small margin, closes back inside range, then breaks above midrange.
- Enter on confirmation close.

Short Entry Rules: Mirror above Asian high.

Stop Loss Logic: Beyond sweep extreme.

Take Profit Logic: Opposite side of range or $1.5R$.

Trade Management: Time stop 60 min; BE after reclaim of midrange.

Filters: Avoid major news, require Asian range width below threshold.

Initial Parameters: Sweep buffer small but above spread noise.

Expected Frequency: 2-5 trades/week.

Why It Might Fail: Strong directional session opens.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: High.

Backtest Acceptance Criteria: Must separate from your existing liquidity-sweep system; otherwise reject.

Pseudocode:

```
if sweep_asian_edge and re-entry_inside_range:  
    trade toward opposite side
```

7) Early NY False Breakout Fade

Market Phenomenon: Early NY breakouts from overnight structure often fail before real direction emerges.

Quant Hypothesis: Breaks of overnight extremes in the first hour after NY open have elevated failure probability unless confirmed.

Why It Could Work on EURUSD: Early US liquidity can probe stops before the market commits.

Trading Window: 07:00-10:00 NY.

Timeframe: M1/M5.

Required Data: Overnight high/low, OHLC, spread, VWAP.

Long Entry Rules:

- Price breaks below overnight low, re-enters range within 3 M1 bars, then closes above trigger bar high.
Short Entry Rules: Mirror above overnight high.
Stop Loss Logic: Beyond failed breakout extreme.
Take Profit Logic: VWAP or midpoint of overnight range, then 1.5R.
Trade Management: One attempt per level; BE at 0.7R.
Filters: No high-impact news; only when overnight range width is moderate, not extreme.
Initial Parameters: Re-entry within 3 bars.
Expected Frequency: 2-6 trades/week.
Why It Might Fail: Real trend days crush fade logic.
Overfitting Risk: High.
Cost Sensitivity: Medium.
Correlation With Liquidity Sweep Strategy: High.
Backtest Acceptance Criteria: Must prove independent edge beyond your existing sweep model.
Pseudocode:

```
if break_of_overnight_edge and quick_reentry:  
    fade_failure
```

8) Late-Session Trend Pullback

Market Phenomenon: Established intraday trend often offers lower-risk pullbacks after the main impulse.

Quant Hypothesis: After a directional move with strong structure, pullbacks to EMA/VWAP in trend direction have positive expectancy.

Why It Could Work on EURUSD: Intraday FX trends often persist through institutional rebalancing and US flow.

Trading Window: 12:00-18:30 NY.

Timeframe: M5/M15.

Required Data: EMA20/50, VWAP, ATR, OHLC.

Long Entry Rules:

- M15 trend up: price above EMA50 and $EMA20 > EMA50$.
- Wait for pullback to EMA20/VWAP zone.
- M5 bullish reclaim candle required.
Short Entry Rules: Mirror.
Stop Loss Logic: Below pullback swing low/high or 1 ATR(M5,14).
Take Profit Logic: 1.5R-2.5R or trailing behind M5 swings.
Trade Management: BE at 1R; max hold 90 min.
Filters: No major news, avoid when trend slope is flat, require ADX or slope filter.
Initial Parameters: EMA20/50, pullback zone within 0.3 ATR of VWAP.

Expected Frequency: 1-4 trades/week.

Why It Might Fail: Trend exhaustion or choppy afternoons.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: Low.

Backtest Acceptance Criteria: Must be profitable on trend-only subsets and near neutral on ranges.

Pseudocode:

```
if trend_up and pullback_to_vwap and reclaim:
    long
```

9) Post-Impulse Pullback Continuation

Market Phenomenon: After a strong impulse, the first orderly pullback often resumes trend.

Quant Hypothesis: The first retracement after a high-momentum leg is a higher-quality entry than chasing the breakout.

Why It Could Work on EURUSD: Trend legs often pause for liquidity refills, then continue if regime remains directional.

Trading Window: 08:30-16:00 NY.

Timeframe: M1/M5.

Required Data: ATR, swing structure, OHLC, volume proxy if available.

Long Entry Rules:

- Identify impulse leg > 1.2 ATR(M15) within 30-90 min.
- Wait for 3-8 bar retrace that holds above prior breakout level.
- Enter on higher low and bullish confirmation.

Short Entry Rules: Mirror.

Stop Loss Logic: Under pullback low.

Take Profit Logic: Extension equal to 1R-2R or measured move.

Trade Management: BE after structure retest succeeds; time stop 60 min.

Filters: Trend regime only; no event risk.

Initial Parameters: Impulse threshold 1.2 ATR; retrace 38-62% of impulse.

Expected Frequency: 1-3 trades/week.

Why It Might Fail: Pullback turns into reversal.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: Low-Medium.

Backtest Acceptance Criteria: Needs clean attribution showing entry quality after impulse, not generic trend following.

Pseudocode:

```
if impulse_detected and retrace_holds_structure:
    enter_with_trend
```

10) Pre-London Trend Alignment

Market Phenomenon: Early session bias can carry into NY when NY opens into established direction.

Quant Hypothesis: If the market trends before NY and remains structured, the first retracement in NY often resumes direction.

Why It Could Work on EURUSD: Europe often sets the day's directional context that NY either extends or redistributes.

Trading Window: 07:00-08:30 NY.

Timeframe: M15/M5.

Required Data: EMA, VWAP, session highs/lows, OHLC.

Long Entry Rules:

- Pre-existing uptrend on M15; higher highs/higher lows intact.
- Enter on NY pullback into EMA20/VWAP with bullish reclaim.

Short Entry Rules: Mirror.

Stop Loss Logic: Beyond pullback swing.

Take Profit Logic: Prior session high/low or 1.5R.

Trade Management: One trade per direction; max hold 90 min.

Filters: Require directional day filter; skip flat VWAP.

Initial Parameters: Trend filter by EMA20 slope > 0.

Expected Frequency: 1-3 trades/week.

Why It Might Fail: NY reverses Europe instead of extending it.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: Low.

Backtest Acceptance Criteria: Must outperform random trend pullbacks, not just look good in a few months.

Pseudocode:

```
if higher_tf_trend and ny_pullback_reclaims:  
    enter_with_trend
```

11) Post-NFP Stabilization Breakout

Market Phenomenon: After NFP shock, a stabilization phase can produce a cleaner secondary directional move.

Quant Hypothesis: The post-spike consolidation after NFP resolves in the direction of the dominant immediate reaction with better reward/risk than the first spike.

Why It Could Work on EURUSD: NFP creates large initial dislocations; the second move after liquidity normalizes can be tradable.

Trading Window: 08:45-10:00 NY on NFP days only.

Timeframe: M1/M5.

Required Data: News calendar, event high/low, spread, OHLC.

Long Entry Rules:

- First shock lower, then 5-15 min stabilization above post-event low.
- Break above stabilization range with spread normalized.

Short Entry Rules: Mirror.

Stop Loss Logic: Opposite side of stabilization range.

Take Profit Logic: 2R minimum, scale at 1R.

Trade Management: Hard time stop 45 min; no trade if spread remains elevated.

Filters: NFP only; skip if first spike already exhausted >2 ATR.

Initial Parameters: Stabilization 5-15 min.

Expected Frequency: Very low.

Why It Might Fail: News slippage, spread spikes, and random reversals.

Overfitting Risk: High.

Cost Sensitivity: High.

Correlation With Liquidity Sweep Strategy: Low.

Backtest Acceptance Criteria: Only if event-specific edge survives conservative execution assumptions.

Pseudocode:

```
if nfp_day and stabilization_done and spread_normal:
    trade_breakout_in_shock_direction
```

12) FOMC Drift-Reentry

Market Phenomenon: After FOMC, market often establishes a drift phase following the first chaotic move.

Quant Hypothesis: Once initial volatility subsides, re-entry in the post-FOMC direction after a pullback can have positive expectancy.

Why It Could Work on EURUSD: FOMC is a major repricing event for USD, and EURUSD often trends after the dust settles.

Trading Window: 14:05-16:30 NY on FOMC days.

Timeframe: M1/M5.

Required Data: News calendar, OHLC, spread, VWAP.

Long Entry Rules:

- Identify dominant FOMC reaction direction after first 10-20 min.
- Wait for pullback to VWAP/EMA20 and reclaim.

Short Entry Rules: Mirror.

Stop Loss Logic: Beyond pullback low/high.

Take Profit Logic: 2R or trend trail.

Trade Management: One attempt only; time stop 90 min.

Filters: Skip if post-event volatility remains chaotic or spread abnormal.

Initial Parameters: Post-event settle 10-20 min.

Expected Frequency: Very low.

Why It Might Fail: FOMC reversals are noisy and regime-dependent.

Overfitting Risk: High.

Cost Sensitivity: High.

Correlation With Liquidity Sweep Strategy: Low.

Backtest Acceptance Criteria: Must be validated by event subtype and time bucket.

Pseudocode:

```
if fomc_day and initial_direction_settled and pullback_reclaims:
    reenter_direction
```

13) Monday NY Mean Reversion

Market Phenomenon: Monday often starts with lower conviction and reverts after early deviation.

Quant Hypothesis: Monday morning deviations from VWAP or opening balance revert more often than midweek.

Why It Could Work on EURUSD: Weekend information digestion can create an early false start.

Trading Window: 07:00-12:00 NY Mondays only.

Timeframe: M5.

Required Data: Day-of-week, VWAP, OHLC, spread.

Long Entry Rules:

- Monday only.
- Price extends below VWAP by threshold and shows rejection candle.
- Trend filter not strongly bearish.

Short Entry Rules: Mirror.

Stop Loss Logic: Beyond excursion low/high.

Take Profit Logic: VWAP or opening price.

Trade Management: Time stop 6-10 bars; partial at VWAP.

Filters: No major news; skip if gap-like behavior or strong trend regime.

Initial Parameters: Deviation threshold 1.0-1.5 sigma.

Expected Frequency: 2-4 trades/month.

Why It Might Fail: Day-of-week effects can vanish out of sample.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: Medium.

Backtest Acceptance Criteria: Must remain positive after removing the best month/year.

Pseudocode:

```
if monday and deviation_extreme and rejection:
    fade_to_vwap
```

14) Friday Afternoon Flattening Edge

Market Phenomenon: Late Friday flows often reduce directional persistence and create reversion or flattening.

Quant Hypothesis: Friday afternoon directional extensions are less durable, especially near weekly levels.

Why It Could Work on EURUSD: Position squaring and reduced weekend risk appetite can alter microstructure.

Trading Window: 13:00-18:30 NY Fridays only.

Timeframe: M5.

Required Data: Day-of-week, weekly high/low, VWAP, OHLC.

Long Entry Rules:

- Price tests downside extension beyond session VWAP/weekly pivot and fails to continue.

Short Entry Rules: Mirror.

Stop Loss Logic: Beyond rejection extreme.

Take Profit Logic: VWAP or 0.8-1.5R.

Trade Management: Strict time stop into close; flatten all before illiquid end-of-day.

Filters: Avoid before major weekend-risk headlines; skip when trend day is obvious.

Initial Parameters: Friday only, after 13:00.

Expected Frequency: 2-5 trades/month.

Why It Might Fail: Friday can also be trend acceleration day.

Overfitting Risk: Medium.

Cost Sensitivity: Low-Medium.

Correlation With Liquidity Sweep Strategy: Medium.

Backtest Acceptance Criteria: Must not rely on one specific quarter or seasonal period.

Pseudocode:

```
if friday_afternoon and extension_fails:
    fade_and_flatten_before_close
```

15) Volatility Regime Breakout Filter

Market Phenomenon: Breakouts work better when volatility regime transitions from compressed to expanding.

Quant Hypothesis: Breakout logic improves materially if conditioned on volatility regime shift rather than raw price alone.

Why It Could Work on EURUSD: EURUSD alternates between quiet and active regimes; entering only when regime changes should reduce false signals.

Trading Window: 07:00-19:00 NY.

Timeframe: M5/M15.

Required Data: ATR percentile, realized volatility, OHLC, spread.

Long Entry Rules:

- Volatility regime: ATR percentile rises from low quartile to middle/higher quartile.
 - Price breaks session structure high with confirmation close.
- Short Entry Rules:** Mirror.
- Stop Loss Logic:** Back inside prior compression zone.
- Take Profit Logic:** 2R or trail.
- Trade Management:** One trade per regime shift; time stop 90 min.
- Filters:** No high-impact news if spread is abnormal.
- Initial Parameters:** ATR percentile lookback 20 days.
- Expected Frequency:** 1-4 trades/week.
- Why It Might Fail:** Regime classification lag.
- Overfitting Risk:** Medium.
- Cost Sensitivity:** Medium.
- Correlation With Liquidity Sweep Strategy:** Low.
- Backtest Acceptance Criteria:** Robust across low/high vol years and not dependent on a single threshold.
- Pseudocode:**

```
if atr_percentile_shift_up and structure_break:
    breakout_trade()
```

16) Trend + Compression Pullback Hybrid

Market Phenomenon: Strong trend plus temporary compression often leads to continuation after pullback.

Quant Hypothesis: In directional regimes, a compression inside trend has better continuation odds than a naked breakout.

Why It Could Work on EURUSD: Traders often wait for compression inside trend to reload, especially during liquid hours.

Trading Window: 07:00-19:00 NY.

Timeframe: M5/M15.

Required Data: EMA, ATR, compression detection, OHLC.

Long Entry Rules:

- Trend up on M15.
 - M5 forms 4-8 bar compression with higher lows.
 - Break above compression high with trend filter intact.
- Short Entry Rules:** Mirror.
- Stop Loss Logic:** Below compression low or trend invalidation level.
- Take Profit Logic:** 1.5R-2.5R.
- Trade Management:** BE at 1R; trail after continuation.
- Filters:** No major news; avoid flat EMA slope.
- Initial Parameters:** Compression 4-8 bars.
- Expected Frequency:** 2-6 trades/week.
- Why It Might Fail:** Compression may simply be distribution before reversal.
- Overfitting Risk:** Medium.
- Cost Sensitivity:** Medium.
- Correlation With Liquidity Sweep Strategy:** Low.
- Backtest Acceptance Criteria:** Distinct from generic breakout and from sweep logic.
- Pseudocode:**

```
if trend and compression_inside_trend and breakout:
    enter_with_trend
```

17) Opening Sweep Failure

Market Phenomenon: Opening moves often sweep a nearby level and then reverse.

Quant Hypothesis: First sweep of prior session high/low near session open fails more than it succeeds in certain regime conditions.

Why It Could Work on EURUSD: Early participation hunts obvious liquidity pools before real allocation emerges.

Trading Window: 07:00-09:00 NY.

Timeframe: M1.

Required Data: Session high/low, OHLC, spread.

Long Entry Rules:

- Sweep below previous low by small margin, immediate reclaim, then bullish close above reclaim level.

Short Entry Rules: Mirror.

Stop Loss Logic: Beyond sweep extreme.

Take Profit Logic: Midrange or opposite side of opening range.

Trade Management: One attempt only; BE quickly.

Filters: Strongly avoid news and strong trend days.

Initial Parameters: Sweep margin above spread noise.

Expected Frequency: 2-6 trades/week.

Why It Might Fail: Same family as your existing sweep strategy; likely high overlap.

Overfitting Risk: High.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: High.

Backtest Acceptance Criteria: Reject if correlated with existing strategy outcomes.

Pseudocode:

```
if opening_sweep and reclaim:
    fade_sweep
```

18) Midday Quiet Range Reversion

Market Phenomenon: Midday NY can be quieter and more range-bound.

Quant Hypothesis: When volatility compresses during midday, deviations from intraday fair value revert.

Why It Could Work on EURUSD: Liquidity is present but conviction often drops after the open and before the last hour.

Trading Window: 11:00-14:00 NY.

Timeframe: M5.

Required Data: VWAP, ATR, OHLC, spread.

Long Entry Rules:

- Price below VWAP by threshold in low-vol regime.
- Rejection candle and failure to continue lower.

Short Entry Rules: Mirror.

Stop Loss Logic: Beyond excursion extreme.

Take Profit Logic: VWAP or midpoint.

Trade Management: Short time stop 30-45 min.

Filters: Not on trend days; no news.

Initial Parameters: Low-vol regime by ATR percentile.

Expected Frequency: 2-8 trades/month.

Why It Might Fail: Midday can also start a delayed trend.

Overfitting Risk: Medium.

Cost Sensitivity: High.

Correlation With Liquidity Sweep Strategy: Medium.

Backtest Acceptance Criteria: Must survive realistic costs and still beat a flat baseline.

Pseudocode:

```
if midday and low_vol and vw ap deviation:  
    fade_to_vwap
```

19) Session High/Low Rejection

Market Phenomenon: Retests of session extremes often reject when no new information exists.

Quant Hypothesis: Rejection of session high/low after failed breakout has positive reversal expectancy.

Why It Could Work on EURUSD: Session extremes are obvious liquidity magnets and often become decision points.

Trading Window: 07:00-19:00 NY.

Timeframe: M1/M5.

Required Data: Session high/low, OHLC, spread, ATR.

Long Entry Rules:

- Price hits session low, closes back above it, then fails to re-break within next 3 bars.
- Enter on reclaim confirmation.

Short Entry Rules: Mirror at session high.

Stop Loss Logic: Beyond extreme plus buffer.

Take Profit Logic: VWAP, range midpoint, or 1.5R.

Trade Management: One attempt per level; BE at 0.7R.

Filters: Avoid trend-day confirmation and news.

Initial Parameters: Rejection confirmation within 3 bars.

Expected Frequency: 2-5 trades/week.

Why It Might Fail: Strong breakout continuation days.

Overfitting Risk: Medium.

Cost Sensitivity: Medium.

Correlation With Liquidity Sweep Strategy: Medium-High.

Backtest Acceptance Criteria: Must show low overlap with sweep strategy and better behavior on clean range days.

Pseudocode:

```
if session_extreme_touched and reclaim_and_fail_rebreak:  
    trade_rejection
```

20) Time-Boxed Trend Exhaustion

Market Phenomenon: Trends late in the day often weaken as participation thins.

Quant Hypothesis: Late-session extensions after a full-day move have lower continuation probability than earlier moves.

Why It Could Work on EURUSD: The market can run out of fresh flow late in NY, especially after a completed trend day.

Trading Window: 15:00-18:50 NY.

Timeframe: M5.

Required Data: Daily range position, ATR, OHLC, spread.

Long Entry Rules:

- Short-term downtrend, but late-session downside extension stalls near daily range extreme.
- Enter long only on reversal confirmation and exhaustion signal.
 - Short Entry Rules:** Mirror.
 - Stop Loss Logic:** Beyond exhaustion extreme.

Take Profit Logic: 1R to VWAP or close.

Trade Management: Mandatory flat by day end; no overnight.

Filters: Strong trend day filter; skip if macro shock.

Initial Parameters: Entry only in last 3-4 hours.

Expected Frequency: 1-4 trades/week.

Why It Might Fail: Late-session trend acceleration or continuation from US headlines.

Overfitting Risk: Medium.

Cost Sensitivity: Low-Medium.

Correlation With Liquidity Sweep Strategy: Medium.

Backtest Acceptance Criteria: Must be robust without relying on Friday-only behavior.

Pseudocode:

```
if late_session and trend_exhaustion and reversal_confirmation:  
    fade_exhaustion
```

5. Top 10 Ranking

1. London Compression Breakout.
2. NY Open Range Expansion.
3. Session VWAP Dislocation.
4. Trend + Compression Pullback Hybrid.
5. Post-Impulse Pullback Continuation.
6. Volatility Regime Breakout Filter.
7. Late-Session Trend Pullback.
8. Session High/Low Rejection.
9. ATR Stretch Snapback.
10. Asia-to-NY Range Failure.

6. Top 5 First Backtest Candidates

1. London Compression Breakout.
2. NY Open Range Expansion.
3. Session VWAP Dislocation.
4. Trend + Compression Pullback Hybrid.
5. Volatility Regime Breakout Filter.

These are the best first tests because they are programmable, not event-only, and more likely to produce enough samples for meaningful validation. They also balance breakout and mean-reversion exposure. For your lab, that matters more than trying to force a niche edge immediately.

7. Top 3 Low-Correlation Candidates

1. Volatility Regime Breakout Filter.
2. Trend + Compression Pullback Hybrid.
3. Pre-Data Compression Release.

These are the most plausibly distinct from “liquidity sweep + structure shift.” The first two are regime/continuation-centered rather than stop-run reversals. The third is event-driven and should behave differently if it survives costs.

8. Top 3 Most Robust Candidates

1. Session VWAP Dislocation.
2. London Compression Breakout.
3. NY Open Range Expansion.

These are the most likely to remain interpretable across years because their logic is broad and tied to intraday market structure. They are not guaranteed profitable, but they are easier to falsify cleanly. That makes them good institutional candidates.

9. Rejected / Dangerous Ideas

- Pure RSI overbought/oversold entries without session or regime context.
- Grid, martingale, and averaging down.
- Ultra-tight scalping that needs unrealistically small spread/slippage.
- News straddles that depend on perfect execution.
- Strategies with 12+ filters added only to improve train PF.
- “Breakout everywhere” systems without compression or regime confirmation.
- Any idea where the edge disappears after 0.5 pip extra slippage.
- Anything whose logic you cannot explain in one sentence.

10. Backtesting Plan

1. **Smoke test:** Run every strategy on a small 2-3 year slice with conservative costs and inspect trade logs, not just PF.
2. **Train-only:** Use 2015-2022 as research train, but freeze 2023-2024 as validation before touching 2025/2026.
3. **Avoid overfitting:** Test one hypothesis family at a time; do not optimize thresholds jointly across 20 strategies.
4. **Choose parameters:** Start from market-logic values, not best-fit values; use wide bins and round numbers.
5. **Cost sensitivity:** Re-run each strategy with +0.2, +0.5, +1.0 pip slippage and wider spreads.
6. **Walk-forward:** Use anchored or rolling WFO with frozen rules per fold; never peek into future folds.
7. **Early rejection:** Reject if edge only exists in one year, one month, or one event type.
8. **Correlation comparison:** Measure trade-sign correlation, PnL correlation, and regime overlap with your sweep strategy.
9. **Prioritize:** Start with broad-session, non-news strategies with enough frequency.
10. **Avoid p-hacking:** Pre-register all thresholds, the acceptance rules, and the order of tests before looking at outputs.

11. Parameter Governance

Freeze parameters in three layers: structural, operational, and risk. Structural parameters define the idea itself, like session window and setup definition; operational parameters define stop/TP and buffers; risk parameters define max daily loss, max open risk, and time exits. Do not change structural parameters after first validation pass. Any parameter change should create a new strategy version with a new ID. Keep a changelog and only compare versions against untouched holdout data.

12. Risk Controls

For FTMO/prop-style constraints, cap daily loss well below the firm limit, not near it. Limit to 1-3 trades/day as you requested, but also cap correlated setups so two “different” strategies cannot fire off the same macro regime. Use a per-day max loss, per-trade max risk, and mandatory flat-at-end-of-window rule. Add news blackout windows, spread filters, and a regime kill-switch if realized slippage drifts above budget. If a strategy is profitable only by holding winners too long, hard time stops should force realism.

13. Final Recommendation

First, test the three broadest and cleanest structures: London Compression Breakout, NY Open Range Expansion, and Session VWAP Dislocation. Second, add one continuation family and one regime-filtered hybrid to diversify away from pure breakout or pure mean reversion. Third, postpone event-only strategies until you have a strong execution model and robust news calendar handling, because those are the easiest place to fool yourself. In parallel, measure overlap with your existing liquidity-sweep system before you scale anything. The best outcome is not one great system; it is a small portfolio of medium edges with low correlation and clear failure modes.
